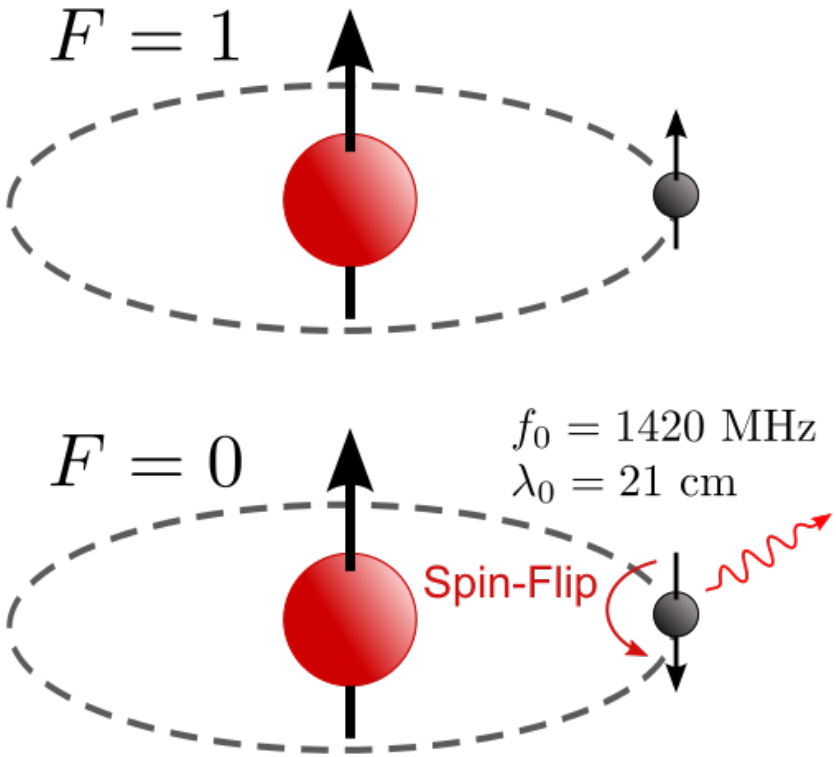
Determining Galactic Strucutre through 21cm Emission Lines

Henry Shackleton

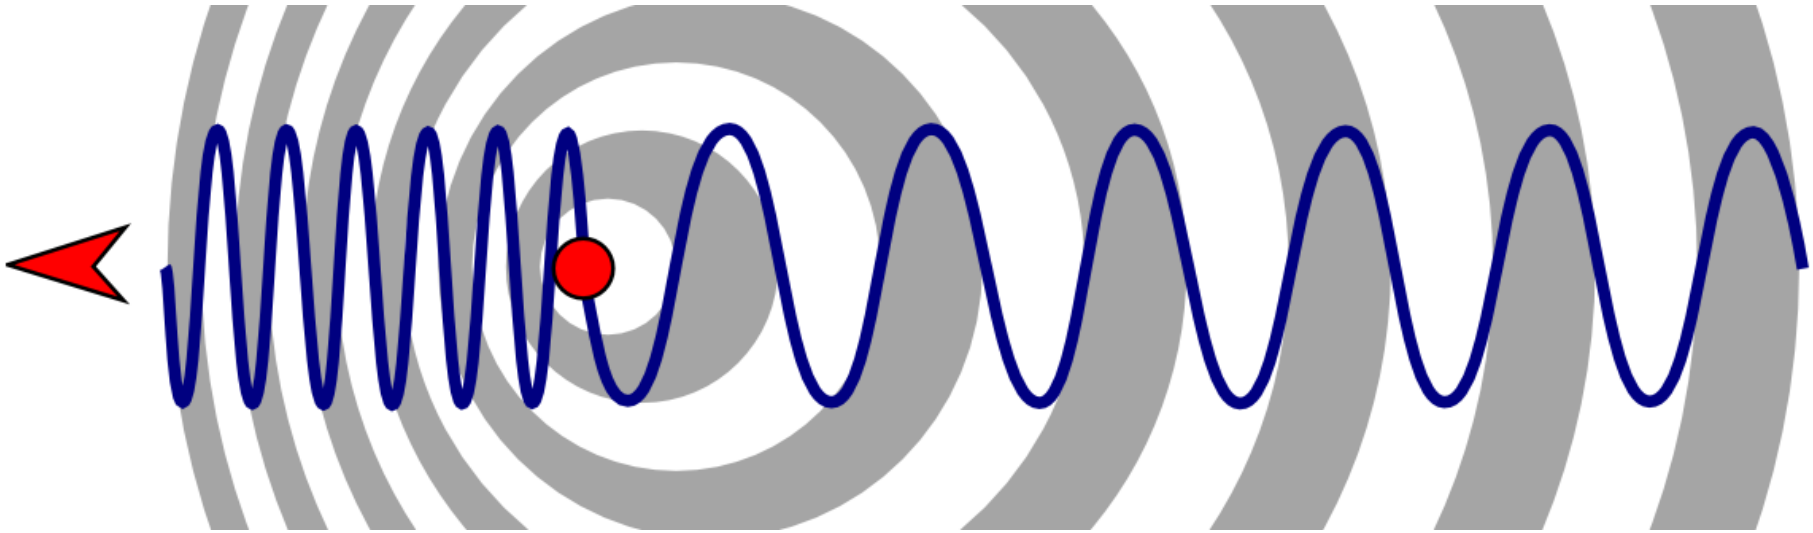
May 10, 2017

Hyperfine Strucutre of Hydrogen Emits 21cm Wavelenth Emission



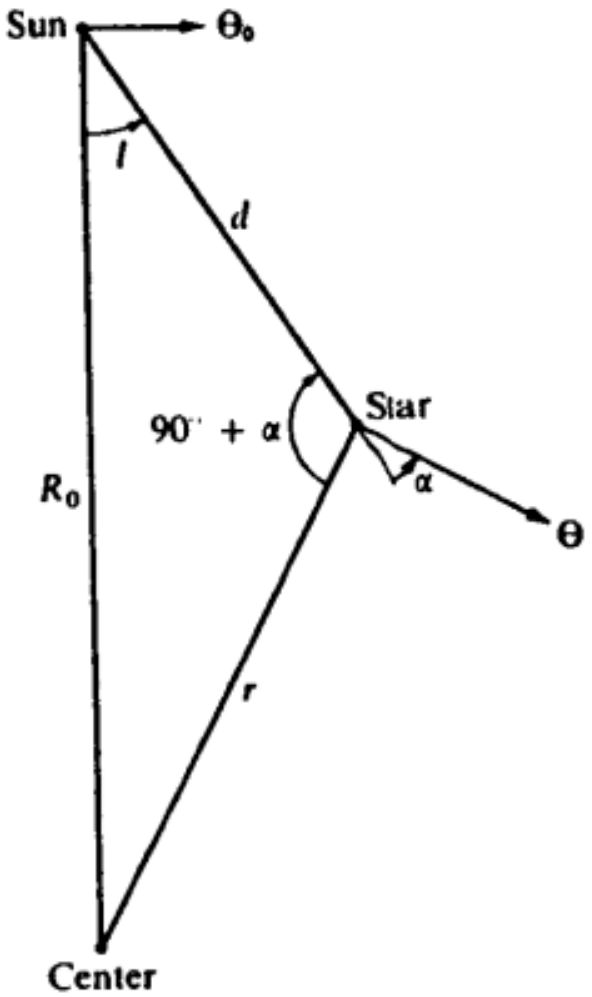
- Hydrogen electron spin-flip causes electromagnetic radiation at a frequency of 1420.41 MHz.
- Low probability ($2.9 \times 10^{-15} s^{-1}$), but the vast amount of hydrogen in the galaxy allows for this detection

Doppler Shift Gives Change in 21cm Line Proportional to Velocity



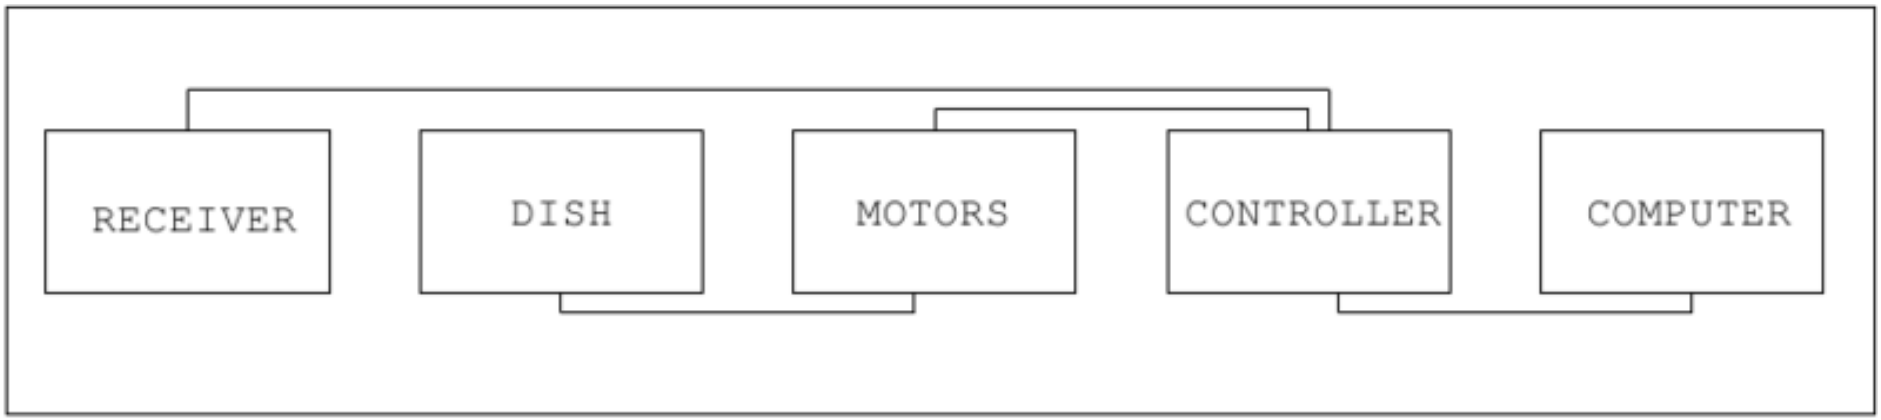
$$v = c\frac{1420.41 - \nu}{\nu}$$

Location of Hydrogen Masses Determined through Geometry



- Velocity we observe is the velocity of the mass *projected* onto our line of sight.
- $v_{obs} = \frac{\Theta}{r} R_0 \sin \ell - \Theta_0 \sin \ell$
- Relation between Θ and r obtained through Galactic Rotation Curve.
- Between $90° < \ell < 180°$, Galactic Rotation Curve is approximately constant.

SRT Measures Radio Power Within Given Frequency Domain



- Noise diode allows for calibration of telescope.
- Recceiver selects desired bandwidth for data collection.
